Abstract. The research integrates methods of assessment and analysis of one facet of psychomotricity, namely the strength and agility expressed in a nonspecific (land-based) environment by junior III water polo players. The focus is on the application of two subtests, subtest 1 – Running speed and agility, and subtest 2 – Strength, which are part of the Bruininks-Oseretsky Test of Motor Proficiency, Second Edition. This test battery was applied to high-performance athletes who were in the sights of the national team and were basic members of their club teams. The athletes are born in 1997, play match by match and belong to Steaua School Sports Club 3 (national champion team) and Emil Racoviță Sports College (ranked 3rd in the national championship). The test was conducted on 7 August 2012 in the sports hall of UNEFS Bucharest. The results have shown that, out of the 24 tested athletes, 87% (21 athletes) fall into the average category, and 13% (3 athletes) fall into the above-average category. Mean composite scores are X = 47.25 points for the athletes from Steaua and X = 53.17 points for those from Steaua. The mean difference is 5.92 points (11.1%) in favour of Steaua athletes. This research has contributed to obtaining, through nonspecific (land-based) means, valuable information on the level of strength and agility of junior III water polo players, which is useful for coaches to introduce technical exercises in their training sessions in order to develop strength and agility under specific competitive conditions and the constant time pressure.

Keywords: strength, agility, water polo, Bruininks-Oseretsky Test.

Introduction

After accessing the Google Scholar database, approximately 4,870 specialised articles on psychomotricity have been identified, which shows an increased interest of specialists in exploring this topic. In the Romanian literature, specialists in the field (Epuran, 1976; Horghidan, 1997; Dragnea & Bota, 1999; Stănescu, 2002; Mitrache & Tüdös, 2004) also studied the issue of psychomotricity. The large number of published studies suggests the permanent interest of experts in clarifying and highlighting the importance of this concept.

We present below a review of the literature on psychomotricity. The conceptual delimitations of psychomotricity converge to emphasise the connection between mental and motor aspects. The interventions of health specialists towards psychomotricity have demonstrated the existence of a constant interaction between motor and mental sides, therefore between body and mind (Azedevo Fernandes et al., 2018). Psychomotricity is a complex function that integrates and combines motor and mental elements (Cojanu & Vișan, 2017). The progressive acquisition of skills related to both mental and motor activities is defined as psychomotor development (Teixeira Costa et al., 2015). Psychomotricity is an expression of
the maturity and integration of mental and motor functions at a level that requires the proper integration of an individual into an environment (Epuran, 1976).

Psychomotricity is a structure whose function expresses complex inter-determinative relationships. Motor and mental aspects mutually condition each other, which is why addressing the motor issue beyond the mental determinants reduces motor acts to automatism. Mental and motor functions are fundamental elements of adaptation. (Dragnea et al., 2006)

Recent studies analysing psychomotricity are focused on motor structures and their relationship with the body schema, ideomotor skills, laterality and spatial-temporal orientation, but also on the means of learning and the social adaptation of the individual (Iconomescu et al., 2017).

The science of psychomotricity is understood as a transdisciplinary field that studies and investigates the mutual and systemic relationships and influences between the psyche and the body, between the psyche and motricity, which are inherent to the unique and evolving human personality that characterises the human being in its multiple and complex biopsychosocial, emotional and social-cognitive manifestations. Psychomotricity starts from a holistic notion of the body and motricity, considering the human being as a complex organism that integrates the soma and the psyche. (da Fonseca, 2010)

Psychomotricity generally studies the human being’s progress and motor acquisitions coordinated by mental activity and achieved by creative, emotional and social development, depending on oneself and the social environment (Talaghir et al., 2019). Psychomotricity allows knowing the human being in terms of interrelation between mental and motor aspects and plays a significant role for the psycho-behavioural system of athletes (Bădău et al., 2010).

Drăgan (2002) highlights that the motor skills necessary for a water polo player, such as explosive power (speed-strength), strength-endurance and endurance-speed (in a permanent back-and-forth movement), give this game a dynamic and spectacular character (like in basketball).

Agility is considered a rapid movement of the whole body, with a change in speed or direction in response to a stimulus (Sheppard & Young, 2006). Generally, the definition of agility is simple but at the same time its context is highly complex, meaning that it can be widely used in practice (Mackala et al., 2020).

Agility plays an important role in both training and competition. Agility is a significant component of performance because it includes the ability to perform fast and efficient movements with the whole body or only with its segments (Verstegen & Marcello, 2001; Holmberg, 2015; Young et al., 2015; Paul et al., 2016; Coh et al., 2018).

While the classical definition of agility refers to the ability of changing the direction or speed of a movement as quickly and precisely as possible, recent definitions have integrated a cognitive component that includes factors such as prediction, visual and perceptual recognition, reaction speed and attention abilities (Coh et al. 2018; Sheppard & Young, 2006). Decision-making and perception are often described as discriminatory factors (Paul et al., 2016).

Agility is an important characteristic of team sports. There is a growing interest in factors that influence agility performance but also in appropriate testing protocols and training strategies to assess and improve this ability (Paul et al., 2016).

Agility has relationships with both motor skills (such as strength and power) and cognitive components (Sheppard & Young, 2006). The comprehensive definition of agility recognises
the importance of motor skills (strength and endurance), cognitive processes (motor learning) and technical abilities (biomechanics) involved in achieving performance (Sheppard & Young, 2006).

It has been demonstrated that, compared to experienced volleyball and basketball players, water polo players have better scores on decision-making, visual reaction time and spatial orientation, while basketball players are better on prediction and selective attention, and volleyball players are better on perceptual speed, focused attention, prediction and estimation of speed and direction of a moving object (Kioumourtzoglou et al., 1998). The study conducted by a group of authors (Oikonomou et al., 2019) has shown that, in young Olympic team players, mixed endurance training and strength training may be associated with a favourable vascular profile.

Botonis et al. (2018) state that the recording of muscle strength level and fitness indices of elite water polo players is of great scientific and practical interest for two reasons: on the one hand, it provides a picture of the upper limits of adaptations derived from long-term water polo training and, on the other hand, it provides scientific evidence to coaches regarding the selection and fitness profile of water polo players.

Given the multitude of dynamic actions that take place throughout a water polo game (physical contact/fight, fast swim, offensive and defensive actions), an appropriate level of strength development is essential for water polo players (Botonis, Toubekis, & Platanou, 2019).

In water polo, daily training lessons in the preparatory period usually include a high volume of interval training along with strength and specific water polo training (Botanies et al., 2019). In the water polo game, athletes must have quick reactions with both dominant and non-dominant hands as they often block the opponent’s shots on goal, which requires explosive movements (Gardasevic et al., 2019).

Research hypothesis

Testing strength and agility through non-specific (land-based) means provides information on the in-water performance of young polo players (junior III).

Methodology

Methods used

This paper is an ascertaining pedagogical experiment, as part of an extensive research of major interest for the field. Among the research methods used, we mention: test method – Bruininks-Oseretksy Test of Motor Proficiency, Second Edition (BOT-2), non-parametric Mann-Whitney U Test, effect size index, graphical method, mathematical and statistical method with the statistical parameters of central tendency, arithmetic mean (X), statistical parameters of dispersion, standard deviation (S), and coefficient of variation (Cv) (Popa, 2008).
Period, site and participants

The present study aims to diagnose the exercise capacity of junior III, the results and the way of achieving them representing a keystone in the efficient training of water polo players. The experiment involved 24 athletes from two water polo clubs in Bucharest, registered in the National Championship: Steaua School Sports Club 3 (CS Steaua) (1st place) and Emil Racoviță Sports College (CS Racoviță) (3rd place). The athletes are born in 1997, play match by match for their club teams and are in the sights of the national team. The test was conducted on 7 August 2012 in the sports hall of UNEFS Bucharest.

The test used

The Bruininks-Oseretsky Test of Motor Proficiency, Second Edition (BOT-2), is an individually administered test battery that relies on a series of very well-defined objectives focused on assessing a wide range of motor skills in subjects aged 4 to 21 years. Since its publication in 1978, the original form of the Bruininks-Oseretsky Test of Motor Proficiency (BOTMP) has been the most widely used test battery to measure psychomotor ability. (Crowe, 1989; Ulrich, 1985) It has gained the trust of specialists in various fields because it is able to provide valuable information on a wide range of motor skills. Moreover, the above test helps evaluators to identify subjects who have certain gaps in motor control, this assessment tool being relatively easy to administer and interpret, and, last but not least, quite agreed by the tested subjects. This test battery was designed for physical therapists, psychologists, physical education teachers, coaches (and not only), providing them with an efficient and reliable instrument for measuring fine and gross motor skills.

Strength and agility: include the coordination and control of large muscle groups involved in locomotion, especially during recreational and competitive activities.

Description of subtests (Gozu, 2011)

Subtest 1: Running speed and agility

Activities in this subtest include running back and forth, jumping on one leg or both legs and crossing the balance beam. During the running speed test (measured in seconds), the examiner has the opportunity to also make clinical observations regarding the quality of subject’s movement.

Content:
- Item 1: shuttle run;
- Item 2: sidestep over the balance beam;
- Item 3: one-leg jumps on the spot;
- Item 4: side jumps on one leg;
- Item 5: side jumps on both legs.
Subtest 2: Strength
Activities in this subtest measure the trunk, upper body and lower body strength. This subtest plays an essential role in the process of assessing motor skills, because strength is an important component of gross motor performance involved in daily activities.

Content:
- Item 1: standing long jump;
- Item 2: full push-ups/push-ups on the knees;
- Item 3: trunk lifts from the supine position with bent knees;
- Item 4: standing with the back against the wall, knees bent at a 90-degree angle;
- Item 5: from lying face down, with arms and legs outstretched, lifting the head, chest, arms and legs simultaneously and holding this position.

Results
Following the analysis and interpretation of the results obtained in subtest 1 (Running speed and agility), we can mention that the minimum value recorded by Racoviță athletes is 8 points, while the maximum value is 17 points, the range of motion being 9 points; the minimum value recorded by Steaua athletes is 10 points, while the maximum value is 21 points, the range of motion being 11 points; the median has the value 11.50 points and the arithmetic mean is 11.92 for Racoviță athletes, while for Steaua athletes, the median has the value 16.50 points and the arithmetic mean is 15.58.

![Bar chart showing comparison of average scores obtained in subtest 1 – Running speed and agility](chart.png)

Figure 1. Comparison of average scores obtained in subtest 1 – Running speed and agility

The mean difference between the scores obtained by both groups of athletes is 3.67 points in favour of the athletes from CS Steaua, which indicates that they are about 23.5% superior in this parameter, and therefore have achieved a higher score in this subtest. In terms of group
homogeneity, the standard deviation is ± 2.94 points and the coefficient of variation is 18.9% for Steaua athletes, which indicates a relative group homogeneity in the tested parameter; the standard deviation is ± 3.40 points and the coefficient of variation is 28.5% for the athletes from CS Racoviță, which indicates that the group lacks homogeneity in the tested parameter. (Table 1 and Figure 1)

Application of the non-parametric Mann-Whitney U Test shows that there are no statistically significant differences between the two groups, $z = -0.247$, $p = 0.013 < 0.05$, but the value of the effect size index (0.51) reveals a large-to-very large difference between the two groups (Table 2).

Figure 2 highlights the percentage scores obtained by each team in the Running speed and agility parameter.

Figure 2. Percentage distribution of scores obtained in subtest 1 – Running speed and agility

Following the analysis and interpretation of the results obtained in subtest 2 (Strength), we can mention that the minimum value recorded by Racoviță athletes is 12 points, while the maximum value is 23 points, the range of motion being 11 points; the minimum value recorded by Steaua athletes is 11 points, while the maximum value is 22 points, the range of motion being 11 points; the median has the value 15 points and the arithmetic mean is 15.92 points for Racoviță athletes, while for Steaua athletes, the median has the value 19.50 points and the arithmetic mean is 18.83 points. The mean difference between the scores obtained by both groups of athletes is 2.92 points in favour of the athletes from CS Steaua, which indicates that
they are about 15.5% superior in this parameter, and therefore have achieved a higher score in this subtest. In terms of group homogeneity, the standard deviation is ± 3.01 points and the coefficient of variation is 16% for Steaua athletes, which indicates a relative group homogeneity in the tested parameter; the standard deviation is ± 3.15 points and the coefficient of variation is 19.8% for the athletes from CS Racoviță, which indicates a relative group homogeneity in the tested parameter. (Table 3 and Figure 3)

Figure 4 highlights the percentage scores obtained by each team in the Strength parameter.
Following the analysis and interpretation of composite scores obtained in the Strength and agility parameter, we can mention that mean composite scores are \( X = 47.25 \) points for the athletes from Emil Racoviță and \( X = 53.17 \) points for those from Steaua. The mean difference between the scores obtained by both groups of athletes is \( X = 5.92 \) points (11.1%) in favour of the athletes from CS Steaua, which indicates that they have achieved a higher score in this subtest. (Table 5 and Figure 5)

**Figure 4.** Percentage distribution of scores obtained in subtest 2 – Strength

**Figure 5.** Comparison of average scores obtained in the Strength and agility parameter

The results range from 46 points to 63 points for CS Steaua athletes and from 41 points to 61 points for CS Racoviță athletes. The coefficient of variation is 13.7% for Racoviță athletes,
which shows that they form a relatively homogeneous group, with large dispersion of results. The coefficient of variation is 9.0% for Steaua athletes, which indicates that they form a homogeneous group, with low dispersion of results.

The non-parametric Mann-Whitney U Test demonstrates that there are statistically significant differences between the two groups, $z = -2.290$, $p = 0.022 < 0.05$. The effect size index (0.49) shows a medium-to-large difference between the two groups. (Table 6)

Figure 6. Percentage distribution of scores obtained in the Strength and agility parameter

Conclusion

General and specific physical training performed on dry land is particularly important for children to increase their in-water motor skills.

In terms of average composite scores, the results obtained by the athletes from CS Steaua are superior (CS Steaua = 53.16; CS Racoviţă = 47.25), the recorded difference being 5.91 points, which is why we consider that the psychomotor abilities gained through non-specific dry-land training are positively transferred to the in-water specific training by improving motor skills and abilities.
Testing strength and agility through non-specific (land-based) means provides information on the in-water performance of young polo players (junior III) – the research hypothesis has been confirmed.

The results achieved in the championship by the athletes from CS Steaua versus the athletes from CS Racoviță are consistent with the results obtained after applying the Bruininks-Oseretsky Test of Motor Proficiency, Second Edition (BOT-2).
